Designation: D4529 – 01 (Reapproved 2006)

Designation: 381/97

Standard Test Method for Estimation of Net Heat of Combustion of Aviation Fuels[1]

This standard is issued under the fixed designation D4529; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the estimation of the net heat of combustion at constant pressure in metric (SI) units, megajoules per kilogram.

1.2 This test method is purely empirical, and it is applicable only to liquid hydrocarbon fuels derived by normal refining processes from conventional crude oil which conform to the requirements of specifications for aviation gasolines or aircraft turbine and jet engine fuels of limited boiling ranges and compositions as described in Note 1.

NOTE 1—The estimation of the net heat of combustion of a hydrocarbon fuel from its aniline point temperature and density is justifiable only when the fuel belongs to a well-defined class for which a relationship between these quantities has been derived from accurate experimental measurements on representative samples of that class. Even in this class, the possibility that the estimates can be in error by large amounts for individual fuels should be recognized. The JP-8 fuel, although not experimentally tested, has properties similar to JP-5 and Jet A fuels and can be considered in the same class. The classes of fuels used to establish the correlation presented in this test method are represented by the following applications:

Fuel	Specification
Aviation gasoline fuels: Grades 80, 82, 100/130, and 115/145	Specification D910 Specification D6227 DEF STAN 91–90 NATO Code F-18
Aviation turbine fuels: JP-4, Avtag/FSII	MIL-DTL-5624 DEF STAN 91–88 NATO Code F-40
JP-5, Avcat/FSII	MIL-DTL-5624 DEF STAN 91–86 NATO Code F-44
JP-8, Avtur/FSII	MIL-DTL-83133 DEF STAN 91–87 NATO Code F-34
Jet A, Jet A-1, Avtur	Specification D1655 DEF STAN 91–91 NATO Code F-35

1.3 The net heat of combustion can also be estimated by Test Method D1405. Test Method D1405 requires calculation of one of four equations dependent on the fuel type with the precision equivalent to that of this test method.

1.4 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Summary of Test Method

3.1 The aniline point, density, and sulfur content of the sample are determined by experimental test methods and the net heat of combustion is calculated using the values obtained by these test methods based on reported correlations.[6,7,8]

4. Significance and Use

4.1 This test method is intended for use as a guide in cases where an experimental determination of heat of combustion is not available and cannot be made conveniently, and where an estimate is considered satisfactory. It is not intended as a substitute for experimental measurements of heat of combustion (Note 2).

NOTE 2—The procedures for the experimental determination of the gross and net heats of combustion are described in Test Methods D240 and D4809.

4.2 The net heat of combustion is a factor in the performance of all aviation fuels. Because the exhaust of aircraft engines contains uncondensed water vapors, the energy released by fuel in vaporizing water cannot be recovered and must be subtracted from gross heat of combustion determinations to calculate net heat of combustion. For high performance weight-limited aircraft, the net heat of combustion per unit mass and the mass of fuel loaded determine the total safe range. The proper operation of the aircraft engine also requires a certain minimum net energy of combustion per unit volume of fuel delivered.

4.3 Because the heat of combustion of hydrocarbon fuel-mixtures are slowly varying functions of the physical properties of the mixtures, the heat of combustion of the mixtures can often be estimated with adequate accuracy from simple field tests of density and aniline point temperature, without the elaborate apparatus needed for calorimetry.

4.4 The empirical quadratic equation for the net heat of combustion of a sulfur-free fuel was derived by the method of least squares from accurate measurements on fuels, most of which conformed to specifications for fuels found in Note 1 and were chosen to cover a range of values of properties. Those fuels not meeting specifications were chosen to extend the range of densities and aniline-point temperatures above and below the specification limits to avoid end effects. The sulfur correction was found by a simultaneous least-squares regression analysis of sulfur-containing fuels among those tested.

5. Procedure

5.1 Determine the aniline point temperature of the sample to the nearest 0.05°C as described in Test Methods D611.

5.2 Determine the density at 15°C of the sample to the nearest 0.5 kg/m^3 as described in Test Methods D941, D1217, D1298, or D4052 or Guide D1250.

5.3 Determine the sulfur content of the sample to the nearest 0.02 mass % sulfur as described in Test Methods D129, D1266, D2622, D3120, D4294, or D5453.

6. Calculation

6.1 Calculate the net heat of combustion using either Procedure A or B.

6.1.1 *Procedure A (By Equation)*—Insert the measured values in (Eq 1) and calculate *Qp*, the net heat of combustion at constant pressure on a sulfur-free basis (Note 3).

$$Qp = 22.9596 - 0.0126587\,A + 26\,640.9\,(1/\rho) + 32.622\,(A/\rho) - 6.69030 \times 10^{-5}(A)^2 - 9\ 217\ 760\,(1/\rho)^2 \quad (1)$$

where:
ρ = density at 15°C, kg/m³,
A = aniline point temperature, °C, and
Qp = net heat of combustion on sulfur-free basis, MJ kg^{-1}.

NOTE 3—In SI units the heat of combustion has the unit J kg^{-1}, but for practical purposes a multiple is more convenient. The megajoule per kilogram (MJ kg^{-1}) is 10^6 J kg^{-1} and is customarily used for the representation of heats of combustion of petroleum fuels, particularly for mixtures such as those covered in this international standard.

6.1.2 *Procedure B (See Table 1)*—Make a linear interpolation between rows bracketing the density and within columns bracketing the aniline point of the sample. Then make a linear interpolation for the aniline point within the row for the calculated density to obtain *Qp*.

6.2 Calculate the net heat of combustion, *Q′p*, corrected for sulfur content in accordance with the following equation:

$$Q'p = Qp - 0.1163\,S \quad (2)$$

where:
S = sulfur content, mass %.

6.3 Calculate the volumetric net heat of combustion in accordance with the following equation:

$$q_p = Q_p\rho \times 10^{-3} \quad (3)$$

where:
q_p = volumetric heat of combustion, MJ L^{-1}.

7. Report

7.1 Report the following information:

7.1.1 Report the result for the net heat of combustion in MJ kg^{-1} to the nearest 0.001.

7.1.2 Report the result for the volumetric net heat of combustion q_p in MJ L^{-1} to the nearest 0.001, if required.

8. Precision and Bias [9]

8.1 *Precision*—The following criteria shall be used for judging the acceptability of estimated heat of combustion results (95 % confidence) when using data on the aniline point temperature, the density, and the sulfur content of a fuel determined by Test Methods D611, D1298, and D129, respectively (Note 4):

8.1.1 *Repeatability*—The difference between two test results, obtained by the same operator with the same apparatus under constant operating conditions on identical test material,

[9] The precision is based on the conversion of data in Test Method D1405 to SI units and the calculations using this test method.

would in the long run, in the normal and correct operation of the test method, exceed the following values only in one case in twenty:

Repeatability	0.012 MJ/kg or 5 BTU/lb

8.1.2 *Reproducibility*—The difference between two single and independent results obtained by different operators working in different laboratories on identical test material would, in the long run, in the normal and correct operation of the test method, exceed the following values only in one case in twenty:

Reproducibility	0.035 MJ/kg or 14 BTU/lb

NOTE 4—Use of fuel property data obtained with greater or lesser precision than that of the test methods indicated will have a like trend on the precision of the predicted heat of combustion.

NOTE 5—As a guide, an estimate of the precision on a volume basis calculated for a fuel with a density of 810.0 kg/m^3 is as follows:

Repeatability	9.7 MJ/m^3
Reproducibility	28 MJ/m^3

8.2 *Bias*—No general statement is made on bias for the test method since the data used to determine the correlation cannot be compared with accepted reference materials.
